# **More Conditionals and Loops**

- Objectives when we have completed this set of notes, you should be familiar with:
  - switch statement
  - the conditional (ternary) operator
  - do-while statement (do-while loop)
  - for statement (for loop)
  - for-each statement (for-each loop)

More Conditionals and Loops - 1

## switch Statement

• Consider the following if statement, where input is a char value:

```
String answer;
if (input == 't') {
    answer = "true";
}
else if (input == 'f') {
    answer = "false";
}
else {
    answer = "invalid";
}
```

COGE

#### switch Statement

 The switch statement is very similar to the if statement (assume input is a char and answer is a String):

```
if (input == 't') {
                         switch(input) {
                             case 't':
  answer = "true";
                                answer = "true";
                                break;
else if (input == 'f') {
   answer = "false";
                              case 'f':
                                 answer = "false";
                                 break;
else {
  answer = "invalid";
                              default:
                                 answer = "invalid";
                           }
```

More Conditionals and Loops - 3

## switch Statement

- Now that you know the syntax, let's look a little more closely
  - Expression in the switch is evaluated

    switch (input) {
    evaluated
    case 't':
  - Its value is matched to
     one of the cases. Suppose
    input is equal to 'f'...
    answer will be set to "false"

    > case 'f':
    answer = "false";
    break;
  - The break statement breaks
    out of the switch
    default:
     answer = "invalid";
  - Note that case 't':, case 'f':, and default: are labels, not executable statements
    TrueOrFalse.java

COCE

More Conditionals and Loops - 4

answer = "true";

#### switch Statement

**Q1** 

- What happens when there is no break statement? Suppose input is 't'
  - It will jump to the switch (input) { appropriate case... > case 't': answer = "true"; And then it will execute case 'f': each statement in the switch until a break or →answer = "false"; the end of the switch default: statement. In this case, →answer = "invalid"; answer will be "invalid" even if input is 't' or 'f'
  - We probably meant to include breaks here, but consider how to print the remaining days in the week using a "fall through" switch (i.e., a switch with one or more missing break statements)
     FallThroughSwitch.java

(33)

More Conditionals and Loops - 5

#### switch Statement

- When to use a switch statement?
  - When checking to see if a result is equal to different values (i.e., a lot of == logic)
  - When you can have alternatives based on an an acceptable switch expression type
- Java 6 and earlier: the switch statement works on the primitive types: char, byte, short, int
  - Java 7 and later: switch statement <u>also</u> works on the wrapper classes of the types above, as well as String and enum types

TaxesWithIfElseIf.java TaxesWithSwitch.java

COCE

#### switch Statement

- Why use a switch statement?
  - Depending on the circumstances, it can reduce a code's visual complexity and possibly the logic
    - Think of the "remaining days of week" example with the fall through switch; an if statement version would have replicated print statements
  - A switch statement can jump directly to the correct case, whereas an if-else-if-else has to evaluate each boolean expression until one is true or all are false
    - In other words, using a switch statement can make your program more efficient
  - Example: consider how the OS handles character input from the keyboard

More Conditionals and Loops - 7

# Conditional (Ternary) Operator \_\_\_\_?\_\_\_:\_\_\_

- Like a concise if-else but an <u>expression</u>: boolean expression ? do this if true : do this if false
- Examples:
  - Print "Right!" Or "Wrong." depending on isCorrect

System.out.println(isCorrect ? "Right!" : "Wrong.");

 Subtract discount (a double) from price (a double) only if discount is above 0

```
double total = (discount > 0) ? (price - discount) : price;
```

• Print " unit" or " units" based on unit

System.out.println("Total: " + units + (units == 1 ? " unit":" units"));

COCH

## **Conditional (Ternary) Operator**

- When to use the ternary operator:
  - It can make a simple *if-else* statement more concise:

```
if (isCorrect) {
    System.out.println("Right!");
}
else {
    System.out.println("Wrong.");
}
can be converted to...
System.out.println(isCorrect ? "Right!" : "Wrong.");
```

More Conditionals and Loops - 9

# **Conditional (Ternary) Operator**

- Conciseness vs. Readability
  - May make the logic of your code hard to follow.
  - The following method returns the number of small bars needed to reach the goal based on small and large chocolate bars available. Having all the logic in a single return expression using multiple ternary operators likely makes the code harder to understand than multiple if statements had been used.

```
public int makeChocolate(int small, int big, int goal) {
   return small - (goal - (big * 5 > goal ? goal / 5 : big) * 5) >= 0
      ? (goal - (big * 5 > goal ? goal / 5 : big) * 5) : -1;
}
```

MakeChoclateExample.java

#### do-while Statement

- do-while loop
  - Similar to a while loop, except that the boolean expression is evaluated at the end of the loop (the do-while statement is a post-test loop whereas the while statement is a pre-test loop)
  - This means the body of the do-while will always be executed at least once, regardless of whether the boolean expression is true

```
do {
  /* code performed on each iteration */
} while (/* boolean expression */);
```

More Conditionals and Loops - 11

#### do-while Statement

- A good use of a do-while is evaluating user input
- Suppose the user is to enter either a y or n, and you want to repeat the request until the input is y or n:

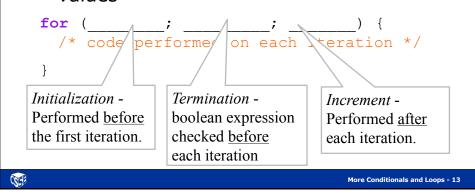

```
Scanner stdIn = new Scanner(System.in);
String yOrN = "";
do {
    System.out.print("Continue? (enter y or n): ");
    yOrN = stdIn.nextLine().trim();
} while (!yOrN.equals("y") && !yOrN.equals("n"));
```

YesOrNoInput.java YesOrNoMaxInput.java

#### for Statement

 for loop - Similar to the while loop, but well-suited for iterating a specific number of times or over a range of values

## for Statement

- Suppose that you wanted code that would calculate the sum of all numbers from 1 to n. (i.e., 1+2+3+...+n)
  - Initialize a sum to 0.
  - Set up an index to count from 1 to n.
  - On each iteration of the loop...
    - Add the current index to a the sum
    - Increment the index
  - Break out of the loop if the index exceeds n.

COGE

#### for Statement

 Suppose that you wanted code that would calculate the sum of all numbers from 1 to n. (i.e., 1+2+3+...+n)

```
int n = 5;
int sum = 0;
for (int i = 1; i <= n; i++) {
   sum += i;
}</pre>
```

AddMultiply.java

More Conditionals and Loops - 15

## for loop vs. while loop

```
// for loop to add 1 to n:
int n = 5;
int sum = 0;
for (int i = 1; i <= n; i++) {
    sum += i;
}

// Equivalent while loop to add 1 to n:
int n = 5;
int sum = 0;
int j = 1;
while (j <= n) {
    sum += j;
    j++;
}</pre>
```

COGE

#### for Statement

 Suppose that list is an ArrayList holding names of type String, and that you wanted to print out each name. You could use the following code:

```
for (int i = 0; i < list.size(); i++) {
    System.out.println(list.get(i));
}</pre>
```

More Conditionals and Loops - 17

## for-each Statement

- An ArrayList is an Iterable object,
   which means it can be the target of the "for-each" statement
- "for-each" (a.k.a. enhanced **for** loop) can be used to loop through list:

```
for (String name : list) {
    System.out.println(name);
}
```

• Read the loop header as:
for each String name in list ...

COGE

#### for-each Statement

 The loop header assigns <u>each</u> String object in order to name. On each iteration, the String object can be accessed using the variable name

```
Type of object held in the ArrayList

For (String name : list) {
System.out.println(name);

GroupRoster.java
```

## break and continue

- A break statement in a loop immediately exits the loop
- The continue statement will skip the rest of the code in that iteration and attempt to do the next iteration of the loop
- Usually the break and continue statements in loops are used in conjunction with an if statement inside a loop

<u>YesOrNoMaxInput.java</u>

BreakForExample.java ContinueForExample.java

# **TriangleListMenuApp**

- Displays a menu of options then uses a
   do-while loop with a switch statement to
   take action based on the user's selection
- Options include:

```
R - Read in File and Create TriangleList
P - Print TriangleList
S - Print Smallest Perimeter
L - Print Largest Perimeter
T - Print Total of Perimeters
A - Add Triangle Object
D - Delete Triangle Object
Q - Quit"
```

TriangleListMenuApp.java (in separate folder)
